

## **Anchovies – A website about movies**

My final project is a website that displays information related to a movie.

The different API's I have used are Rotten Tomatoes, OMDb and Spotify. All of them return (or have the option to do so) data in JSON format that is later processed.

The website is built using jQuery and Bootstrap for the frontend.

Depending on what the user types, he/she will be presented with the different results that match the search. Then one of these will be selected and the data will be populated. This data involves different sections that will be filled with the data retrieved from the calls to the API's.

As a prerequisite, there has to be a file called "key.json" in the root folder containing the Rotten Tomatoes key in the format {"rotten": "value"}, although I have included the key in the code too in case reading the file caused last-minute problems.
